Discussion of Marginal Effects Analysis

The main text of this article discusses the considerable extent to which our hypotheses regarding the influence of distinct forms of governmental support for religion (GRS) influence confidence in the Church by members of Christian-majority countries' religious majority and religious minorities. Statistical analyses describe the results of our multilevel ordered logit regressions via odds ratios, matching data from the Religion and State project, round 3 (RAS3) to country-level surveys conducted by the World Values Survey between 1990 and 2014.

The odds ratio approach allows us to estimate the probability that increasing scores in each form of GRS should increase or decrease the degree of confidence reported by majority or minority participants in the Church. This statistic offers an *overall* estimate of how changes in values of our key independent variables, namely levels of general religious funding, exclusive religious funding for the majority religion, and entanglement between religious institutions and the state relate to popularly expressed confidence in the Church.

We are able to provide an even more refined estimates using marginal effects analyses. These analyses tell us the likelihood that increasing levels of each time of GRS measured will result in participants reporting confidence in the Church at *each* possible level, from the lowest degree of confidence at 1 to the highest at 4. This degree of detail offers further empirical support for the hypotheses presented in the main text. We have however relegated these discussions to the Appendix so as not to overwhelm non-statistically minded readers with technical details. Results for each of our six models, counterposing predicted effects between majority and minority religionists, are visually presented in Figure A1, with all plots presented with 95% confidence intervals. Specific marginal effects for each level of confidence in the Church for each model are found in Table A3.

Regarding general religious funding, we confirm the analysis presented in the main text that while increasing general funding for religion increases majority religionist confidence in the Church, it decreases minority religionist confidence. As in the main text, the substantive strength of these tests is not considerable, but they remain statistically significant. For members of the religious majority, increasing levels of general funding predict decreasing probability of about 0.2% of reporting the lowest possible level of confidence in the Church (score 1), but increasing probability of reporting the highest possible confidence in the Church (score 4) by about 0.5%. By contrast, for members of religious minorities, each increasing level of general funding predicts an increasing probability of the lowest possible level of confidence in the Church by about 0.9% but a decreasing probability of reporting the highest possible confidence in the Church by about 1.7%.

Regarding exclusive religious funding, we offer even stronger confirmation of the magnitude of the hypothesized effect, namely that increasing religious funding exclusivity leads to greater disenchantment by both religious majorities and minorities in the Church. For members of the religious majority, this translates to an increasing probability of about 1.4% of reporting the lowest level of confidence in the Church and a decreasing probability of about 4.2% of reporting the highest level of confidence in the Church given increased religious funding exclusivity. Minorities follow the same pattern with even more substantive effect, with an increasing probability of about 3.7% of reporting the lowest level of confidence in the Church and a decreasing probability of about 7.5% of reporting the highest level of confidence given increased religious funding exclusivity.

Finally, we confirm the opposing trends of confidence in the Church for religious majorities and minorities discussed in the main text, given increasing religious institutional entanglement. This effect is not particularly substantively strong, but still quite significant for the majority, with an increasing probability of about 0.5% in expressing the lowest level confidence in the Church and an decreasing probability of about 1.5% given increased religion-state entanglement. For members of religious minorities, this effect is quite a bit stronger, with decreasing probabilities of about 2.6% of expressing the lowest confidence in the Church and with increasing probabilities of about 4.5% of expressing the highest confidence in the Church given increased religion-state entanglement.

Table A3. Average Marginal Effects on Confidence in the Church
